

How do wind turbines work?

There are other two control mechanisms attached to a modern big wind turbine. Controlling the orientation of the turbine blade. Controlling the orientation of the turbine face. The turbine blades are adjusted from their base hub using a system of gears and small motors or hydraulics. This system, called pitch control, can be electric or mechanical.

How do wind turbine blades work?

The turbine blades are adjusted from their base hub using a system of gears and small motors or hydraulics. This system, called pitch control, can be electric or mechanical. It swivels the blades to align with wind speed, ensuring they capture the most wind energy efficiently.

How a turbine rotor works?

When the wind strikes the rotor blades, blades start rotating. The turbine rotor is connected to a high-speed gearbox. Gearbox transforms the rotor rotation from low speed to high speed. The high-speed shaft from the gearbox is coupled with the rotor of the generator and hence the electrical generator runs at a higher speed.

How is exciter current controlled in a wind turbine?

The exciter current is controlled by a turbine controller which senses the wind speed. Then output voltage of electrical generator (alternator) is given to a rectifier where the alternator output gets rectified to DC.

The working principle involves the drive pulley rotating along with the motor shaft, transferring motion to the turbine shaft. This rotational energy is then converted into electrical power ...
